ABSTRACT:

PURPOSE: To improve the production rate and workability in the production of a crosslinked polymer, by effecting a radical aqueous solution polymerization which finely dividing, with a shearing force, a hydrated gel-like crosslinked polymer formed with the progress in polymerization and continuously discharging the formed polymer.

CONSTITUTION: A polymerization initiator and an aqueous solution of a monomer which, when polymerized in an aqueous solution, forms a hydrated gel-like polymer by the formation of a crosslinking structure are continuously fed to a vessel having a plurality of rotary agitator shafts. The radical aqueous solution polymerization is effected while the hydrated gel-like polymer formed with the progress in polymerization is being finely divided with a shearing force by the rotation of the agitator shafts. The formed divided

hydrated gel-like polymer is continuously discharged from the vessel. It is preferable that the aqueous monomer solution fed to the polymerization vessel has a concentration of 10-80wt%. It is necessary that the vessel has a plurality of rotary agitator shafts, and examples of these vessels include double-arm kneader and three-screw kneader.

ABSTRACT:

PURPOSE: To obtain a water-absorbing resin having high water-absorption ratio, low content of water-soluble component and residual monomer and high safety, by polymerizing a monomer containing an acid group and having a neutralization ratio falling within a specific range.

CONSTITUTION: A monomer component containing $\geq 50\text{mol}\%$ of a monomer having acid group [e.g., (meth)acrylic acid or 2-acrylamide-2-methylpropanesulfonic acid] wherein $10\text{--}50\text{mol}\%$ of said acid group-containing monomer is neutralized (preferably a monomer component containing $0.001\text{--}5\text{mol}\%$ of a crosslinkable monomer having ≥ 2 polymerizable double bonds) is polymerized in a reactor having plural

rotary stirring shafts furnished with stirring blades to obtain the objective water-absorbing resin. A resin having further improved water-absorption ratio can be produced by adding one or more neutralizing agents selected from a basic substance and a weak acid salt to the obtained hydrated polymer gel to raise the neutralization ratio of the polymer to $\geq 50\text{mol}\%$.
